

Aggregating with `group_by()` and `summarize()`

Each row in `student_df` represents a student, but what if we wanted to understand how each grade performs?

Let's dissect some code...

"Summarize each grade level by number of students and average post assessment score."

```
1 student_df %>%  
2   group_by(Grade) %>%  
3   summarize(  
4     Students = n(),  
5     Average_Post_Assessment_Score = mean(Post.Assessment.Score)  
6   )
```

Let's dissect some code...

"Summarize each grade level by number of students and average post assessment score."

```
1 student_df %>%  
2   group_by(Grade) %>%  
3   summarize(  
4     Students = n(),  
5     Average_Post_Assessment_Score = mean(Post.Assessment.Score)  
6   )
```

group_by()

Specify how you want your data to be grouped (what will each **row** represent)

Let's dissect some code...

"Summarize each grade level by number of students and average post assessment score."

```
1 student_df %>%  
2   group_by(Grade) %>%  
3   summarize(  
4     Students = n(),  
5     Average_Post_Assessment_Score = mean(Post.Assessment.Score)  
6   )
```

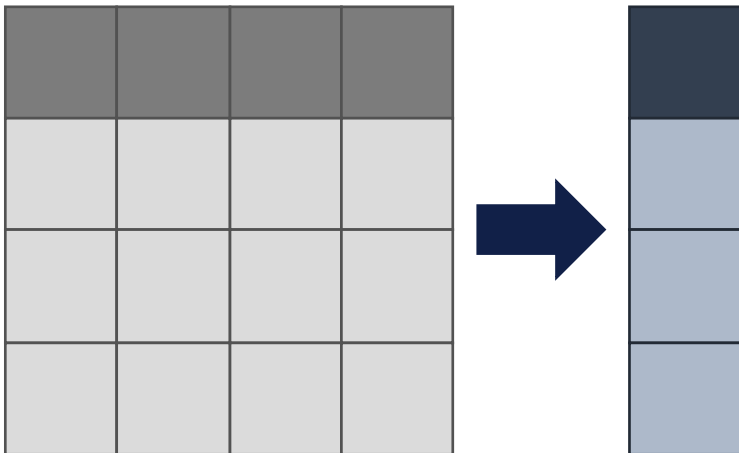

summarize()

Specify how you want your data to be grouped (what will each **column** represent)

At first glance, `summarize()` might seem similar to `mutate()`, but...

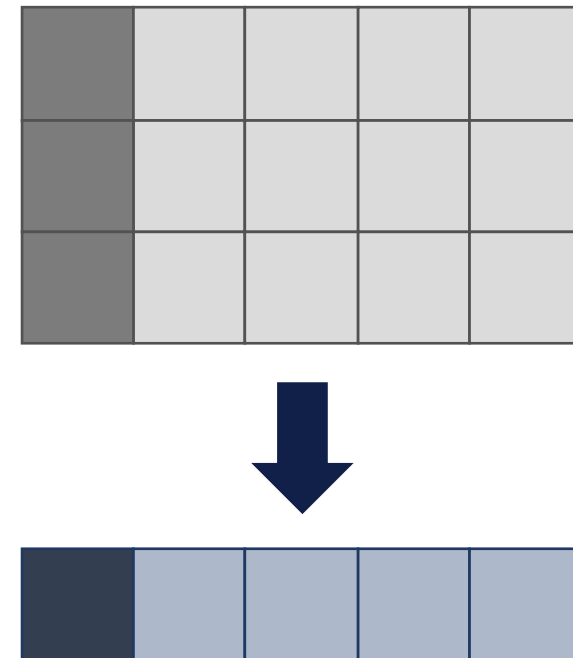

`mutate()`

Applies calculation across columns

`summarize()`

Applies calculation across rows

Demo

`summarize()` and `group_by()`

Summarize each grade level.

Knowledge Check

Summarize

True or False:

You can use `summarize()` and `mutate()` interchangeably.

Knowledge Check

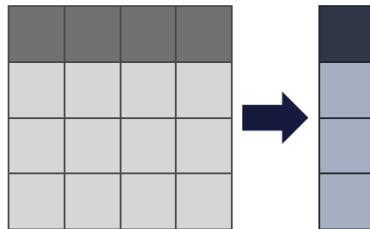

Summarize

True or False:

You can use `summarize()` and `mutate()` interchangeably.

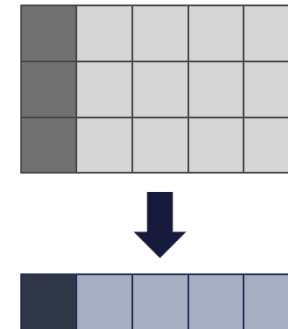

`mutate()`

Applies calculation across columns

`summarize()`

Applies calculation across rows
