

Assumptions

You shouldn't try to memorize every R function.

You shouldn't try to memorize every R visualization.

You shouldn't try to memorize every **statistical test**.

...But you do need to know what assumptions they make!

Types of Tests:

Parametric: Makes assumptions about the distribution of the outcome (or model errors)

Example: t-test

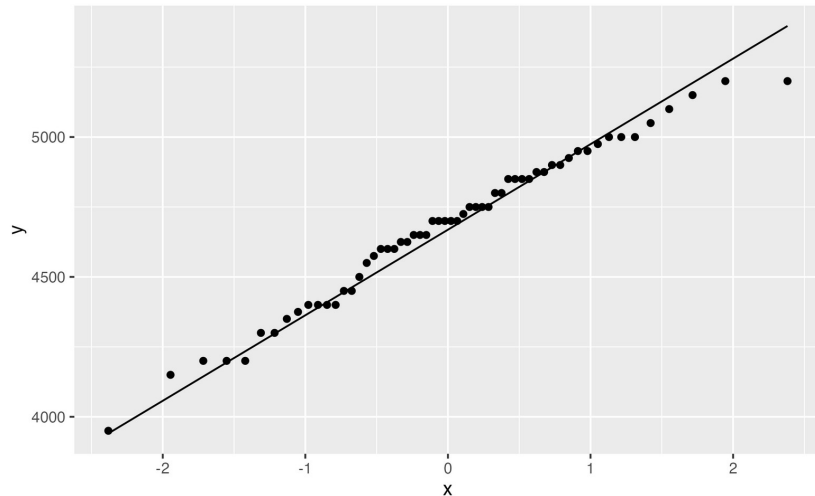

Non-parametric: Makes fewer assumptions about the outcome distribution

Example: Wilcoxon rank-sum test

One assumption we may need to consider is the distribution of the outcome.

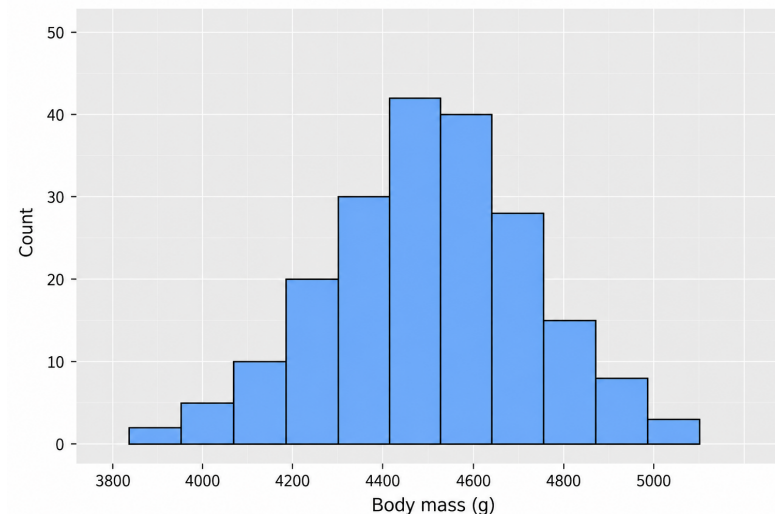

QQ Plot

Points close to the diagonal line suggest approximate normality.

Histogram

Look for strong skewness or unusual values.
